CONNECTOR FOR DESIGNSYNC MILKYWAY

OBJECTIVE

Connector for DesignSync® Milkyway provides design data management for Synopsys® Milkyway data by integrating **Software and System-on-a-Chip Designer** and design tools included in the Synopsys Galaxy Design Platform such as Astro™ and JupiterXT. ™

OVERVIEW

Software and System-on-a-Chip Designer is extended with a capability to recognize and efficiently manage Synopsys design data stored in a Milkyway database. The Synopsys Galaxy Design Platform is modified with the addition of Synchronicity® menus and commands.

Designers are able to perform design data management (DDM) operations such as check-in, checkout, or tag without leaving the familiar Synopsys design environment, and without having to manage the actual collections of files and directories on disk, which represent Synopsys design view types such as place and route abstracts (FRAM) or physical layouts (CEL).

Most importantly, **Connector for DesignSync Milkyway** allows companies to leverage the efforts of multiple designers on a single Milkyway database, eliminating the need to maintain multiple copies. Because physical design generates large amounts of data, the potential for disk savings alone is enormous.

HIGHLIGHTS

Key features and capabilities include:

EDA Data Awareness – Synopsys Library Recognition

Data awareness is important because data created and modified by Electronic Design Automation (EDA) tools, such as the Synopsys Astro place and route tool, is not stored on disk as a single file. Rather, a design object such as an Astro layout consists of a specific set of files.

In order for a DDM system to maintain a version history of changes to a layout, this set of files must be managed as a group. The group of files is also referred to as a "co-managed" set, or "collection object." These collection objects are stored in a larger directory structure called a "library." A Synopsys "library" consists of "view types," such as a place and route abstracts (FRAM) or layouts (CEL), each of which can represent multiple design objects. A binary "catalog" file is included as well, and the set of all the directories and files which represent the library are collectively referred to as the Milkyway database.

Connector for DesignSync Milkyway extends **Software and System-on-a-Chip Designer** with a capability to recognize Synopsys Milkyway libraries on disk and not confuse them with ordinary directories and files. Collection objects are managed transparently to the end user, and a local binary catalog file is maintained so that a valid Milkyway data structure exists in the workspace.

When a user issues a command to checkout a version of a layout, the catalog is updated, and the appropriate versions of each of the member files of the collection object are checked out automatically. The member files of the collection are each individually version controlled, and a mapping is maintained between the version of the design object and the versions of the member files which constitute the version of the object. Storage of data in the DDM repository is efficient because only member files of a collection which are modified in an edit operation are stored in the new version of the design object. And because the design object is managed as a "collection," the tool prevents direct modification to individual member files, which can result in the corruption of the object as a whole.

When **Software and System-on-a-Chip Designer** is enabled with **Connector for DesignSync Milkyway**, Synopsys data recognition becomes evident since users operate on familiar constructs such as libraries, view types, and cell views.

Support for Tagging Methodologies

Every engineer has stories of bad files overwriting good files, and of the taped-out configuration being lost during the test run. Support for tagging the Milkyway database at various milestones allows users to take snapshots of known good configurations to safeguard against such occurrences. Libraries or individual cells may be tagged. Tagging is especially useful for data handoffs, making it easy for the recipient to know which version of a cell or library to fetch.

The ability to tag libraries at various stages of development also alleviates the need to make copies of the entire library to retain these stages. Because Synopsys libraries can become extremely large, the ability to tag various versions of a library instead of copying the library can result in enormous disk space savings.

Multiple DDM User Interface

Software and System-on-a-Chip Designer menus are included in the Synopsys Galaxy Platform environment's "Cell Checkout" and "Library Tag" forms. The "Export Library Information" form enables one to extract technology or reference library information from the binary database into ASCII files which can be modified. Changes can then be "Imported" back into the binary database, and a revision history is maintained. Alternatively, DDM commands for Synopsys Galaxy Platform can be performed through the **Software and System-on-a-Chip Designer** user interface. This flexibility supports many different use models.

Design Collaboration Enabled

Collaboration in the Synopsys Galaxy Platform environment is complicated by the fact that the underlying Milkyway database cannot be directly shared by multiple users. The database is entirely binary. In addition to design data, the Milkyway database includes user specific information, complicated technology information, and reference library dependencies. Only **Connector for DesignSync Milkyway** supports an environment in which multiple users working in individual workspaces can collaborate on a single Milkyway database, which is stored in the DDM repository. Synopsys Application Programming Interface (API) functions are utilized to construct local user workspaces in a manner in which design objects, technology information, and reference library pointers can be revision controlled as a project evolves. The Milkyway database can be tagged at important milestones, facilitating data handoffs, and eliminating the need to make copies of the database in order to revert to a previous state.

Efficient Disk Space Usage

Because **Connector for DesignSync Milkyway** provides the capability to collaborate on a single Milkyway database, it is not necessary to make copies of databases for any user who wishes to contribute changes. Because of the potential for Milkyway databases to become extremely large, the potential for disk space savings is enormous.

Purging Data from the Repository

The data repository can be cleaned up by purging old versions of objects. A "purge" command deletes specified versions of an object on a single branch in the vault. Purging data results in disk space savings in the data repository.

Support for Tagging Methodologies

The ability to tag libraries at various stages of development also alleviates the need to make copies of the entire library to retain these stages. Because Synopsys libraries can become extremely large, the ability to tag various versions of a library instead of copying the library can result in enormous disk space savings.

Manage the Project Technology File

An ASCII technology file must be loaded into the binary Milkyway database. Over the course of a project, parameters in the technology file may be changed. **Connector for DesignSync Milkyway** can extract the technology file from the database into an ASCII file which can be edited, and then re-imported while maintaining the revision history of changes.

Manage the Project's Reference Libraries

Pointers to reference libraries are also maintained in the binary Milkyway database. The set of reference libraries may change over the course of a project. **Connector for DesignSync Milkyway** provides the means for extracting the reference library information from the database into an ASCII file which can be edited, and the re-imported, such that a revision history of the reference library pointers file is maintained.

Viewing Version History

The complete version history of a cell view may be viewed.

Our **3D**EXPERIENCE® platform powers our brand applications, serving 12 industries, and provides a rich portfolio of industry solution experiences.

Dassault Systèmes, the **3D**EXPERIENCE® Company, provides business and people with virtual universes to imagine sustainable innovations. Its world-leading solutions transform the way products are designed, produced, and supported. Dassault Systèmes' collaborative solutions foster social innovation, expanding possibilities for the virtual world to improve the real world. The group brings value to over 190,000 customers of all sizes in all industries in more than 140 countries. For more information, visit **www.3ds.com**.
